

# **Litter Dynamics and Particulate Organic Matter Fractions in Smooth Bromegrass Pastures Under Reduced Nitrogen Inputs** John A. Guretzky<sup>1</sup>, Walter H. Schacht<sup>1</sup>, Ana Wingeyer<sup>1</sup>, and Terry J. Klopfenstein<sup>2</sup>

<sup>1</sup>Dept. of Agronomy and Horticulture, University of Nebraska-Lincoln <sup>2</sup>Dept. of Animal Science, University of Nebraska-Lincoln

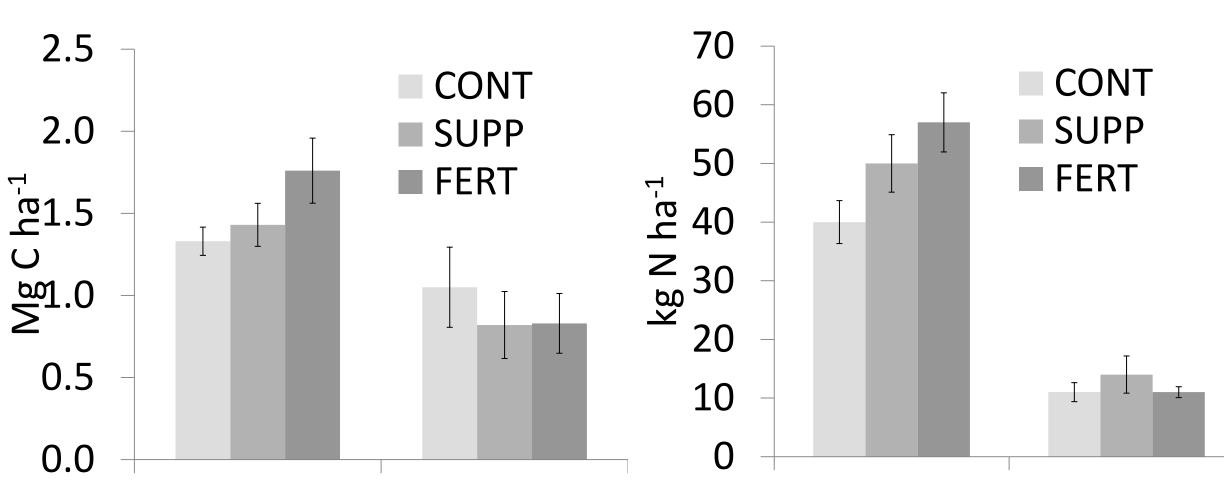

#### OBJECTIVE

Determine how supplementation of rotationally stocked beef cattle with corn (Zea mays L.) dried distillers grains plus solubles (DDGS) in unfertilized pasture affects litter dynamics and particulate organic matter fractions relative to unsupplemented beef cattle rotaionally stocked on unfertilized (CONT) and N fertilized (FERT) smooth bromegrass (Bromus inermis

<u>Nitrogen budget</u>							
		Treatment					
Item	Source	CONT	SUPP	FERT			
		———— kg N ha <sup>-1</sup> ————

## Root/rhizome C and N

#### HYPOTHESIS

Greater herbage trampling and senescence in FERT would increase litter and soil particulate organic matter fractions relative to CONT and SUPP.

#### MATERIALS AND METHODS

#### Management systems

Yearling cattle rotationally stocked within

- Unfertilized pasture at 6.4 AUM ha<sup>-1</sup> (CONT);
- Unfertilized pasture at 9.9 AUM ha<sup>-1</sup> and supplemented with 2.3 kg DDGS steer<sup>-1</sup> d<sup>-1</sup> (SUPP);
- N-fertilized pasture at 9.9 AUM ha<sup>-1</sup> (FERT).

#### RESULTS

Herbage mass

FERT supports more herbage mass, stocking rates, and

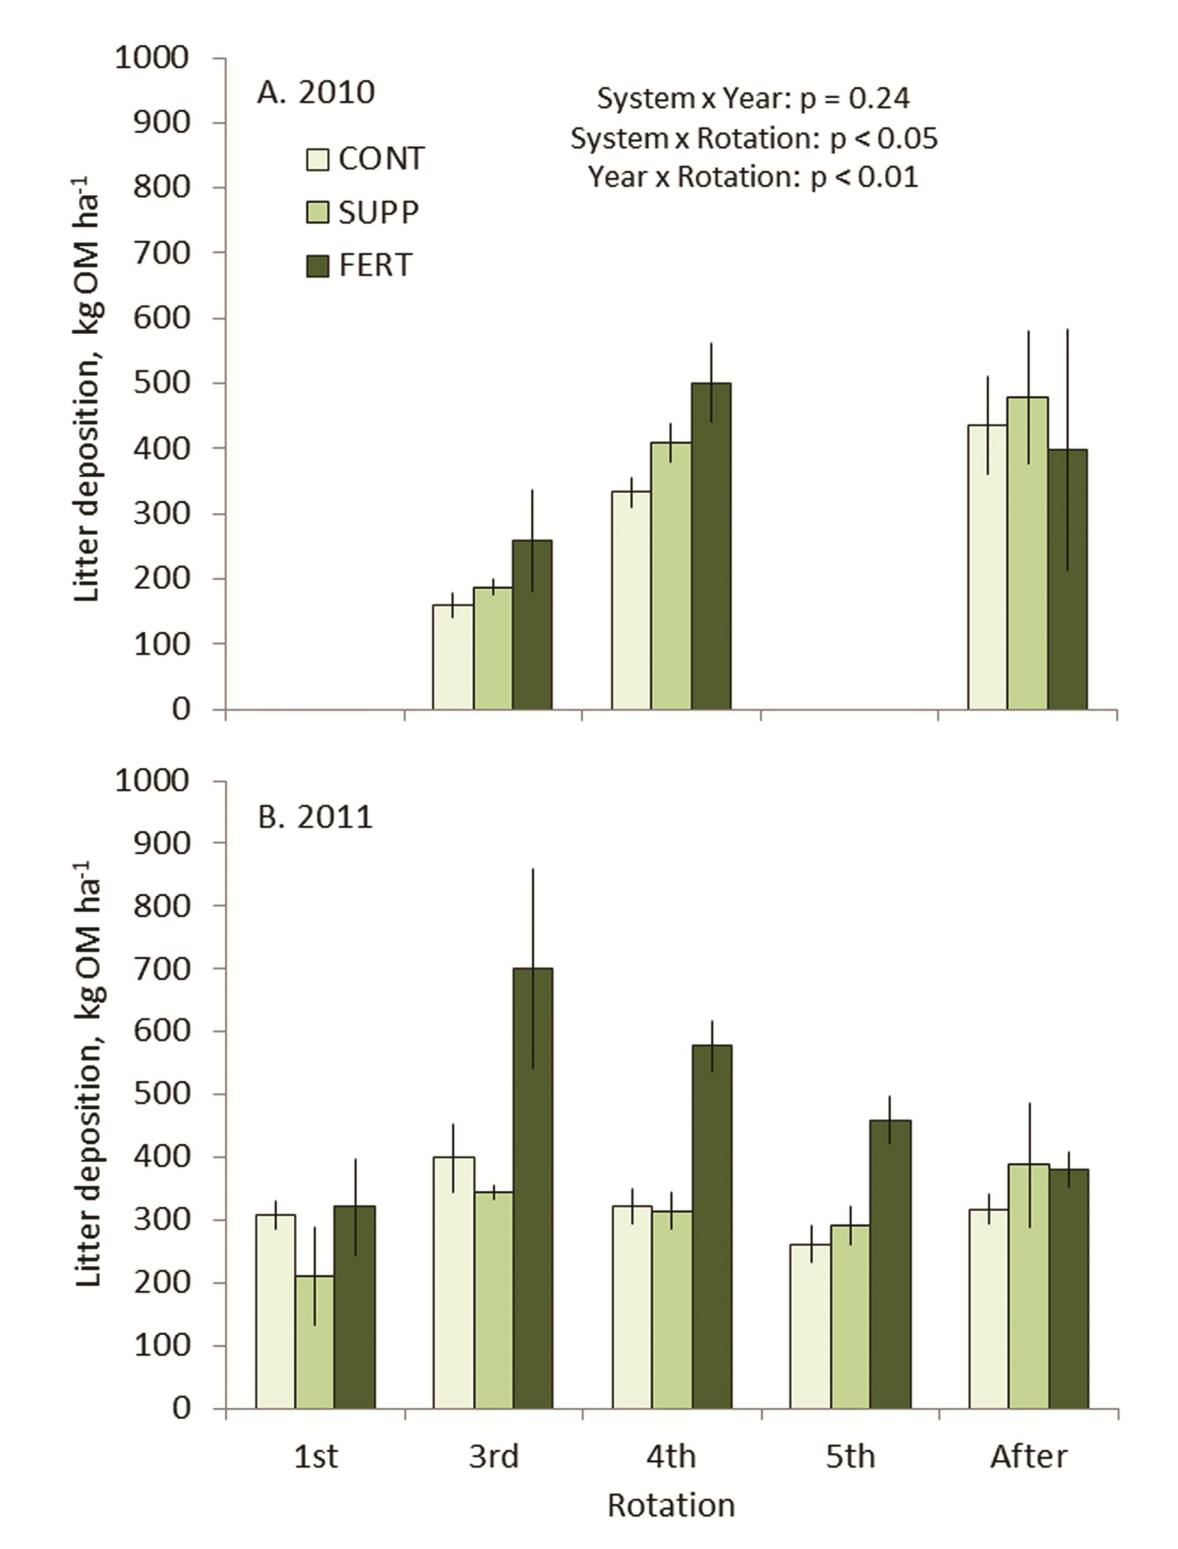

+ DDGS N fed = kg AUD<sup>-1</sup> × 4.6% N × final stocking rate.

‡ National Atmospheric Deposition Program

§ Herbage N consumption = % herbage N × intake × stocking rate (AUD) ha<sup>-1</sup>);

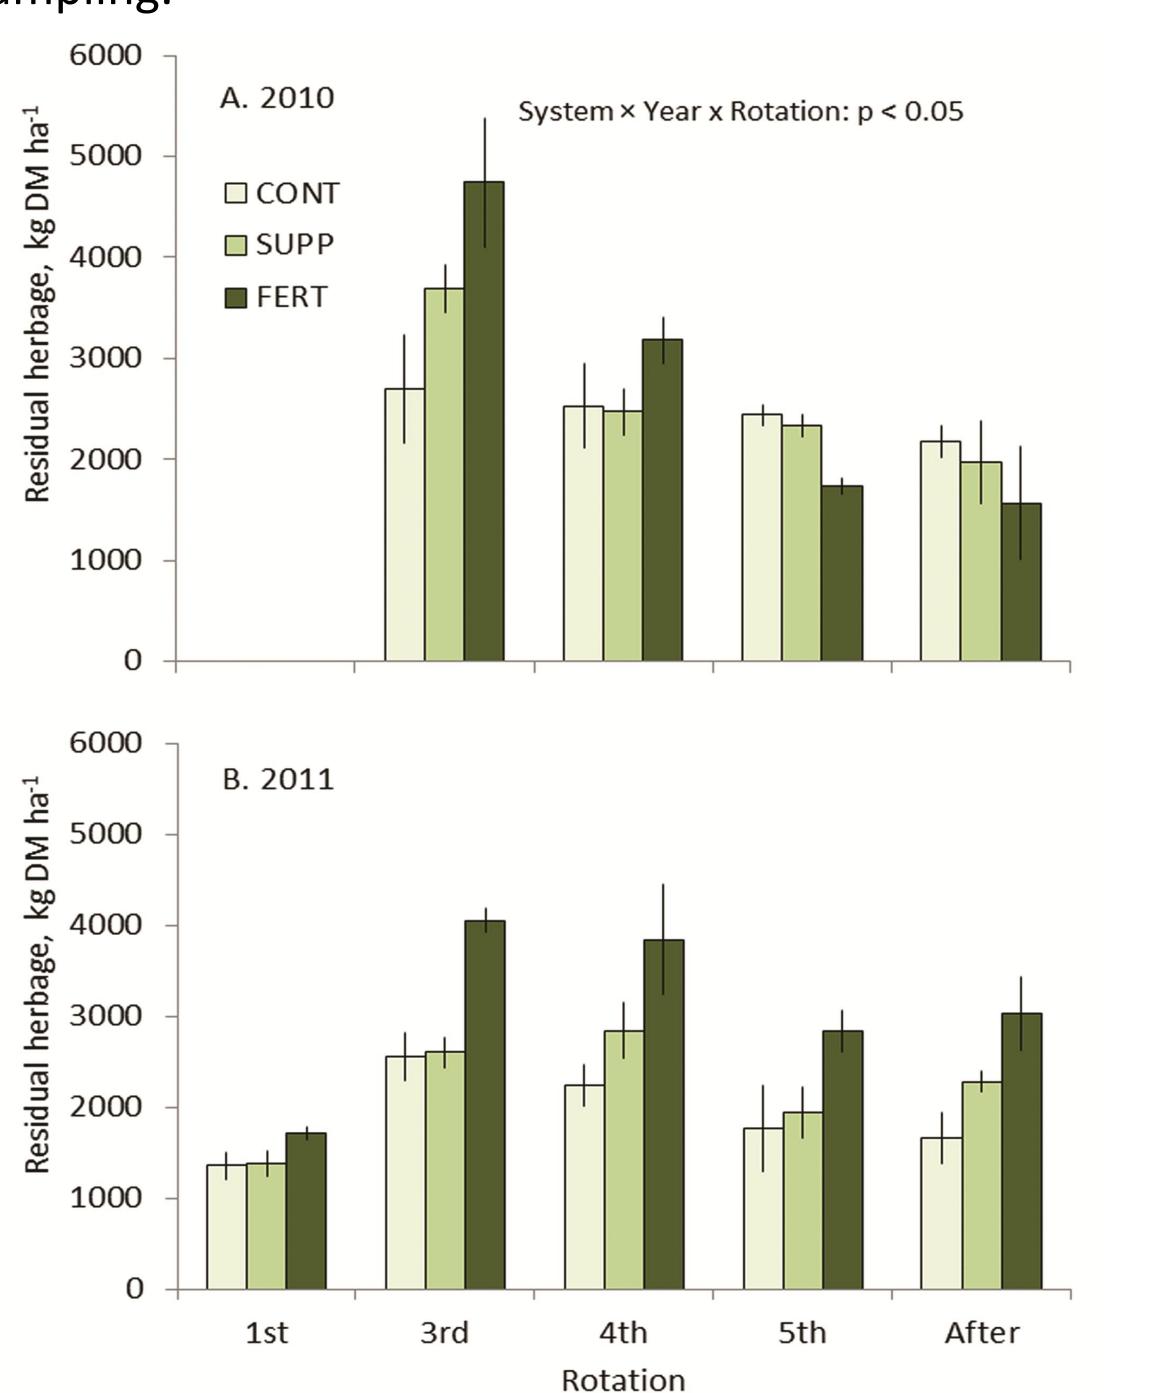

¶ Nitrogen retention = N retained AUD<sup>-1</sup> × stocking rate. Nitrogen retained calculated from NRC (1996) equations. # Nitrogen excretion = N consumption – N retention ++ N balance (surplus) = total N inputs – N retention

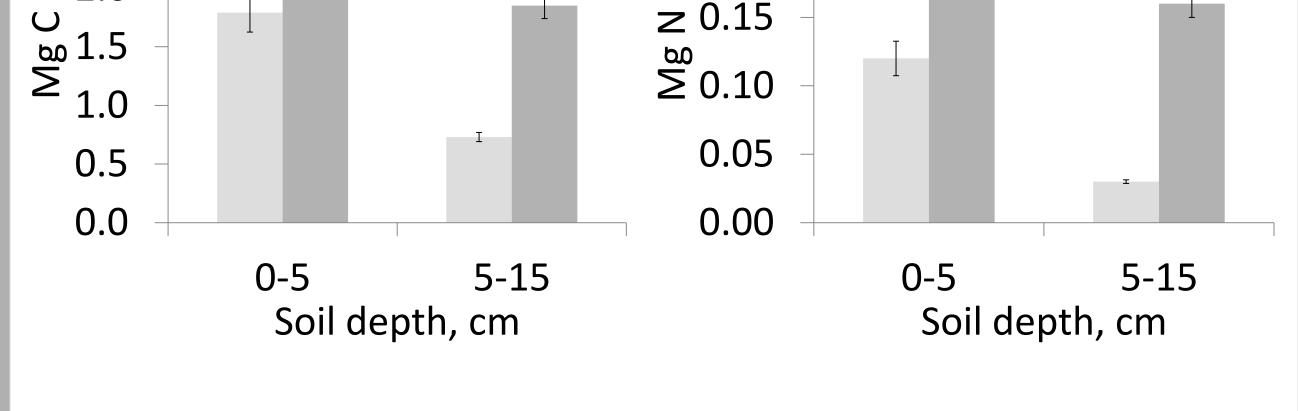

### Litter deposition

#### CONCLUSION

- SUPP reduces N inputs and improves animal NUE.
- FERT produces more herbage, litter, and root/rhizome mass.
- Systems with equal cumulative grazing pressures maintain similar soil organic C and total N.
- Increased litter deposition in FERT may reduce annual weeds (Guretzky et al. 2013)
- Reduced litter N return relative to excreta in SUPP may increase N losses.

158-d grazing season, equivalent to 35%, 23%, and

34% of total N returning through litter and excreta in

CONT, SUPP, and FERT, respectively.
